

DOM Manipulation (adding functionality to HTML elements)

1. Create a rectangular container.
2. Create three buttons below the container named as changeColor, addChild and removeChild (buttons).
3. Give css to the container like width, height, and background color etc.
4. Retrieve the container and the button objects and give functionality to the buttons.
5. When clicked on changeColor button, the color of the container should be changed.
6. When clicked on addChild button, a new square box should be added inside the parent container (rectangular box which is created earlier).
7. The parent container should have flex property.
8. When clicked on the removeChild button, the last added square box child should be removed/disappeared.
